Motivation

Third-party data sharing is a widespread practice in the digital economy

- ∼ Firms collect consumer data as by-product of ordinary transactions
- ∼ Firms may later sell this data to third parties, who use it for advertising, credit, pricing, etc.

Motivation

Third-party data sharing is a widespread practice in the digital economy

- ∼ Firms collect consumer data as by-product of ordinary transactions
- ∼ Firms may later sell this data to third parties, who use it for advertising, credit, pricing, etc.

This practice developed amid limited restrictions on what data could be collected, sold, and used ⇝ **Data Anarchy** FTC '14, FTC '24

Motivation

Third-party data sharing is a widespread practice in the digital economy

- ∼ Firms collect consumer data as by-product of ordinary transactions
- ∼ Firms may later sell this data to third parties, who use it for advertising, credit, pricing, etc.

This practice developed amid limited restrictions on what data could be collected, sold, and used ⇝ **Data Anarchy** FTC '14, FTC '24

This raises welfare concerns

- ∼ Firms may profit from selling data even when its use harms consumers
- ∼ And consumers may forgo purchases they would otherwise value

Motivation: Data Bans

A natural policy response is to ban third-party data sales $\rightsquigarrow$ **Data Ban**

- $\sim$ If consumers dislike having their data sold and used, a data ban removes the harm directly

Motivation: Data Bans

A natural policy response is to ban third-party data sales $\rightsquigarrow$ **Data Ban**

- $\sim$ If consumers dislike having their data sold and used, a data ban removes the harm directly

However, if selling data is valuable, seller may reduce product prices to acquire more data

- $\sim$ Thus, a data ban may harm consumers by making products more expensive

Motivation: Data Markets

Another policy response is to give consumers more control over their data:

- ∼ How? Enable firms to credibly promise not to sell consumer data
- ∼ Firms could then offer different versions of the same product, differing in whether/how data will be monetized
- ∼ Different product prices will implicitly compensate consumers for their data ⇝ **Data Market**

Motivation: Data Markets

Another policy response is to give consumers more control over their data:

- How? Enable firms to credibly promise not to sell consumer data
- Firms could then offer different versions of the same product, differing in whether/how data will be monetized
- Different product prices will implicitly compensate consumers for their data $\rightsquigarrow$ **Data Market**

However, sellers with market power may use this additional screening tool to extract more consumer surplus

Motivation: Data Markets

Another policy response is to give consumers more control over their data:

- How? Enable firms to credibly promise not to sell consumer data
- Firms could then offer different versions of the same product, differing in whether/how data will be monetized
- Different product prices will implicitly compensate consumers for their data $\rightsquigarrow$ **Data Market**

However, sellers with market power may use this additional screening tool to extract more consumer surplus

This Paper

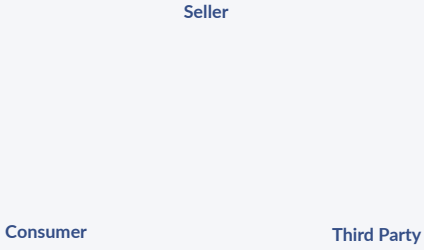

1. A tractable framework to study third-party data sharing

- ∼ It draws on mech and info design to jointly determine product prices, data disclosure, and downstream data use

- ∼ It draws on mech and info design to jointly determine product prices, data disclosure, and downstream data use

2. Use this framework to study the welfare effects of regulation

- ∼ Anarchy, Ban, or Market?

Preview of Results

A key parameter shapes equilibrium and policy:

- $\sim$ The **privacy** $\beta \rightsquigarrow$ It governs whether consumers with higher WTP for seller's good have higher ($\beta > 0$) or lower ($\beta < 0$) WTP for privacy

Preview of Results

A key parameter shapes equilibrium and policy:

- The **privacy** $\beta \rightsquigarrow$ It governs whether consumers with higher WTP for seller's good have higher ($\beta > 0$) or lower ($\beta < 0$) WTP for privacy

In particular,

- If $\beta > 0$, eqm data sharing is **coarse** and more data use **hurts** consumers
- If $\beta \leq 0$, data sharing is **granular** and more data use **benefits** consumers

Preview of Results

A key parameter shapes equilibrium and policy:

- ∼ The **privacy** β ⇝ It governs whether consumers with higher WTP for seller's good have higher ($\beta > 0$) or lower ($\beta < 0$) WTP for privacy

In particular,

- ∼ If $\beta > 0$, eqm data sharing is **coarse** and more data use **hurts** consumers
- ∼ If $\beta \leq 0$, data sharing is **granular** and more data use **benefits** consumers

Without further structure, each regime can be best for all consumers

- ∼ We derive structural conditions that resolve these welfare comparisons
- ∼ **Data market** is robust compromise with many desirable welfare properties

model

Model: First Period

The seller has a single indivisible good for sale

$\theta \in [0, 1]$ is the consumer's valuation for this good, distributed with CDF F

Model: First Period

The seller has a single indivisible good for sale

$\theta \in [0, 1]$ is the consumer's valuation for this good, distributed with CDF F

Seller announces a (deterministic) **mechanism** $(x, t) : M \to \{0, 1\} \times \mathbb{R}$

- $\rightsquigarrow$ If $x(m) = 0$, product is not allocated, game ends, payoffs are zero
- $\rightsquigarrow$ If $x(m) = 1$, product is allocated, game moves to next period

Model: First Period

The seller has a single indivisible good for sale

$\theta \in [0, 1]$ is the consumer's valuation for this good, distributed with CDF F

Seller announces a (deterministic) **mechanism** $(x, t) : M \to \{0, 1\} \times \mathbb{R}$

- $\sim$ If $x(m) = 0$, product is not allocated, game ends, payoffs are zero
- $\sim$ If $x(m) = 1$, product is allocated, game moves to next period

In the latter case, we refer to message m as the consumer's **data record**

Model: Second Period

Seller makes a tioli offer to sell access to record m to third party at price $p(m)$

Model: Second Period

Seller makes a tioli offer to sell access to record m to third party at price $p(m)$

Third party can verify the value of the record, but she obtains access to the consumer only if she buys the record

Model: Second Period

Seller makes a tioli offer to sell access to record m to third party at price $p(m)$

Third party can verify the value of the record, but she obtains access to the consumer only if she buys the record

If record m is not sold, the game ends

Model: Second Period

Seller makes a tioli offer to sell access to record m to third party at price $p(m)$

Third party can verify the value of the record, but she obtains access to the consumer only if she buys the record

If record m is not sold, the game ends

If record m is sold, the third party

- $\sim$ gains access to the consumer and interacts with her by taking action $a \in \mathbb{R}$
- $\sim$ we interpret action a as **data use** — e.g., intensity of third-party advertising

Model: Second Period

Seller makes a tioli offer to sell access to record m to third party at price $p(m)$

Third party can verify the value of the record, but she obtains access to the consumer only if she buys the record

If record m is not sold, the game ends

If record m is sold, the third party

- $\sim$ gains access to the consumer and interacts with her by taking action $a \in \mathbb{R}$
- $\sim$ we interpret action a as **data use** — e.g., intensity of third-party advertising

Note: seller controls whether data are sold, but cannot contract on their use

Data Policies

We compare three alternative policy environments:

- **Data Anarchy**. The seller **cannot commit** to the second-period data-pricing strategy $p : M \to \mathbb{R}$
- **Data Market**. The seller **can commit** to the second-period data-pricing strategy $p : M \to \mathbb{R}$
- **Data Ban**. The seller **cannot sell** consumer data to the third party

Payoffs: Seller

The **seller**'s payoff is

$$t(m) + p(m)$$

the revenue from selling **the good** to consumer and **the data** to third party

Payoffs: Seller

The **seller**'s payoff is

$$t(m) + p(m)$$

the revenue from selling **the good** to consumer and **the data** to third party

Payoffs: Third Party

The **third party**'s payoff is

$$v(\theta, a) = a\theta - \frac{1}{2}a^2$$

Thus, optimal a is posterior mean of θ

Payoffs: Third Party

The **third party**'s payoff is

$$v(\theta, a) = a\theta - \frac{1}{2}a^2$$

Thus, optimal a is posterior mean of θ

Our results extend to payoffs $v(\theta, a)$ such that:

- The third party's optimal action is a strictly increasing and concave function of posterior mean
- The third party's indirect value of a record is a positive and strictly convex function of posterior mean

Payoffs: Consumer

Type-θ consumer's payoff from reporting m when third party's action is a:

$$x(m)\Big(\theta - a \cdot \ell(\theta)\Big) - t(m),$$

$\ell(\theta)$ is type-θ's marginal disutility from data use $\rightsquigarrow$ **privacy loss** (1-dim type)

Instrumental (as opposed to intrinsic) preference for privacy

Payoffs: Consumer

Type-θ consumer's payoff from reporting m when third party's action is a:

$$x(m)\Big(\theta - a \cdot \ell(\theta)\Big) - t(m),$$

$\ell(\theta)$ is type-θ's marginal disutility from data use $\rightsquigarrow$ **privacy loss** (1-dim type)

Instrumental (as opposed to intrinsic) preference for privacy

For this talk, I'll focus on **affine** and **positive** privacy loss function

$$\boxed{\ell(\theta) = \alpha + \beta\theta \geq 0}$$

I refer to the slope parameter as the "**privacy β**"

Our results extend to monotone and convex ℓ

Payoffs: Consumer

Type-θ consumer's payoff from reporting m when third party's action is a:

$$x(m)\Big(\theta - a \cdot \ell(\theta)\Big) - t(m),$$

$\ell(\theta)$ is type-θ's marginal disutility from data use $\rightsquigarrow$ **privacy loss** (1-dim type)

Instrumental (as opposed to intrinsic) preference for privacy

Instrumental (as opposed to intrinsic) preference for privacy

If β positive: Consumers who value good more are **more** averse to data use

i.e., there is a **positive** correlation between valuation and privacy loss

Example: Downstream price discrimination

Payoffs: Consumer

Type-θ consumer's payoff from reporting m when third party's action is a:

$$x(m)\Big(\theta - a \cdot (\alpha + \beta\theta)\Big) - t(m),$$

$\ell(\theta)$ is type-θ's marginal disutility from data use $\rightsquigarrow$ **privacy loss** (1-dim type)

Instrumental (as opposed to intrinsic) preference for privacy

If β positive: Consumers who value good more are **more** averse to data use

i.e., there is a **positive** correlation between valuation and privacy loss

Example: Downstream price discrimination

discussion

Discussion

Important assumptions:

- One-dimensional consumer type θ

  Type θ jointly affects the consumer's valuation for good, her privacy loss, and how valuable she is to third party

- Analysis focuses on deterministic mechanisms

Less important assumptions:

- All-or-nothing disclosure, disclosure of records is verifiable
- Functional forms

the economics of third-party data sharing

Outcomes

Let an *outcome* (or direct mechanism) be described by (x, t, a) where

- $x : \Theta \to \{0, 1\}$ is the allocation
- $t : \Theta \to \mathbb{R}$ is the payment
- $a : \Theta \to A$ is the (recommended) data use

Outcomes

Let an *outcome* (or direct mechanism) be described by (x, t, a) where

- $x : \Theta \to \{0, 1\}$ is the allocation
- $t : \Theta \to \mathbb{R}$ is the payment
- $a : \Theta \to A$ is the (recommended) data use

An outcome (x, t, a) is

- *individually rational* (IR) if $U(\theta) \geq 0$ for all θ
- *incentive compatible* (IC) if $U(\theta) \geq u(\theta, \theta')$ for all θ, θ'
- *obedient* (OB) if $\tilde{a} \in \arg\max_{a'} \mathbb{E}\big(v(\theta, a') \mid a(\theta) = \tilde{a}\big)$ for all $\tilde{a} > 0$

Implementable Outcomes

An outcome is *implementable* in a policy regime if it can be induced by an equilibrium for that regime

Implementable Outcomes

An outcome is *implementable* in a policy regime if it can be induced by an equilibrium for that regime

Remark 1

An outcome (x, t, a) is implementable under

1. Market iff it is IR+IC+OB
2. Anarchy iff IR+IC+OB, and every buyer's data is sold $x(\theta) = 1 \Rightarrow a(\theta) > 0$
3. Ban iff it is IR+IC+OB, and no data is sold $(a \equiv 0)$

Implementable Outcomes

An outcome is *implementable* in a policy regime if it can be induced by an equilibrium for that regime

Remark 1

An outcome (x, t, a) is implementable under

1. Market iff it is IR+IC+OB
2. Anarchy iff IR+IC+OB, and every buyer's data is sold $x(\theta) = 1 \Rightarrow a(\theta) > 0$
3. Ban iff it is IR+IC+OB, and no data is sold $(a \equiv 0)$

1. Seller can commit to data-pricing strategy $\Rightarrow$ Standard application of RP

Implementable Outcomes

An outcome is *implementable* in a policy regime if it can be induced by an equilibrium for that regime

Remark 1

An outcome (x, t, a) is implementable under

1. Market iff it is IR+IC+OB
2. Anarchy iff IR+IC+OB, and every buyer's data is sold $x(\theta) = 1 \Rightarrow a(\theta) > 0$
3. Ban iff it is IR+IC+OB, and no data is sold $(a \equiv 0)$

2. Seller can't commit to data-pricing strategy: Each record has positive value for TP $\Rightarrow$ it will be sold $\Rightarrow a(\theta) > 0$ if $x(\theta) = 1$

Implementable Outcomes

An outcome is *implementable* in a policy regime if it can be induced by an equilibrium for that regime

Remark 1

An outcome (x, t, a) is implementable under

1. Market iff it is IR+IC+OB
2. Anarchy iff IR+IC+OB, and every buyer's data is sold $x(\theta) = 1 \Rightarrow a(\theta) > 0$
3. Ban iff it is IR+IC+OB, and no data is sold $(a \equiv 0)$

3. Seller can't sell records $\Rightarrow a \equiv 0$ (OB is vacuous)

Implementable Outcomes

An outcome is *implementable* in a policy regime if it can be induced by an equilibrium for that regime

Remark 1

An outcome (x, t, a) is implementable under

1. Market iff it is IR+IC+OB
2. Anarchy iff IR+IC+OB, and every buyer's data is sold $x(\theta) = 1 \Rightarrow a(\theta) > 0$
3. Ban iff it is IR+IC+OB, and no data is sold $(a \equiv 0)$

Implication: Seller's revenue is weakly higher in a data market

How Privacy β Affects Consumer Rents

Question: Does a policy leading to an increase in data use (i.e., a pointwise increase in $a : \Theta \to \mathbb{R}$) benefit or hurt consumers, keeping x fixed?

How Privacy β Affects Consumer Rents

Question: Does a policy leading to an increase in data use (i.e., a pointwise increase in $a : \Theta \to \mathbb{R}$) benefit or hurt consumers, keeping x fixed?

Recall consumers dislike data use by assumption (since $\ell(\theta) \geq 0$)

Yet, *in equilibrium*, more data use is not necessarily bad for consumers, since transfers adjust when data use changes

The question is whether the transfer adjustment compensates consumers for their privacy loss

How Privacy β Affects Consumer Rents

The answer reveals the importance of the privacy β

Proposition 1

Among implementable outcomes with the same allocation rule x:

- If $\beta \geq 0,$ an increase in data use **decreases** consumer payoff $U(\theta)$ for all θ
- If $\beta \leq 0,$ an increase in data use **increases** consumer payoff $U(\theta)$ for all θ

How Privacy β Affects Consumer Rents

The answer reveals the importance of the privacy β

Proposition 1

Among implementable outcomes with the same allocation rule x:

- If $\beta \geq 0,$ an increase in data use **decreases** consumer payoff $U(\theta)$ for all θ
- If $\beta \leq 0,$ an increase in data use **increases** consumer payoff $U(\theta)$ for all θ

Economic Implication:

- $\sim$ Optimal policy should discourage data use when $\beta > 0$
- $\sim$ Optimal policy should encourage data use when $\beta \leq 0$

How Privacy β Affects Consumer Rents

Intuition: Consider the following thought experiment

- Fix an allocation x and suppose data use increases uniformly
- Seller will then lower t (uniformly) to keep marginal purchaser indifferent
- Inframarginal purchaser benefits from price reduction (lower t) but suffers a privacy loss (higher a)
- When $\beta > 0$, higher types suffer more from privacy loss than the marginal type and are therefore undercompensated
- When $\beta < 0$, higher types suffer less and thus are overcompensated

How Privacy β Shapes Data Sharing

So far, we have held the allocation rule x fixed

The seller's incentive to serve additional consumers depends on how their data can be monetized

To understand this, we next characterize what kind of data sharing is feasible

Here, too, the sign of the privacy β plays a central role

How Privacy β Shapes Data Sharing

Proposition 2

Consider any policy regime in which data sales are permitted:

- If $\beta > 0$, third-party data sharing is "**coarse**"

  In any implementable outcome, at most one data record is sold; this record pools all types of consumers whose data is sold

- If $\beta \leq 0$, third-party data sharing can be "**granular**"

  There is an implementable outcome in which a continuum of data records is sold, each revealing a unique consumer type

How Privacy β Shapes Data Sharing

Economic Implications:

- If $\beta > 0$

  Consumers whose data is sold must experience **the same** data utilization, and are compensated equally, even if the value of their data is different, and even if their WTP for privacy differs

- If $\beta < 0$

  Consumers whose data is sold can experience **different** data utilization, and thus can be compensated differently

How Privacy β Shapes Data Sharing

Intuition: If $\boxed{\beta > 0}$

- $\rightsquigarrow$ IC $\Rightarrow$ seller must ensure that $a(\theta)$ is **decreasing** on the set of trading types

  High types are more privacy sensitive, so they must not be assigned more data use to prevent deviations

- $\rightsquigarrow$ OB + monotone $a \Rightarrow$ seller must ensure that $a(\theta)$ is **increasing** on the set of trading types

  Higher types call for higher actions from third party

Thus, IC and OB are **in conflict** $\rightsquigarrow$ coarse disclosure

How Privacy β Shapes Data Sharing

Intuition: If $\beta < 0$

- $\sim$ IC $\Rightarrow$ seller must ensure that $a(\theta)$ is **increasing** on the set of trading types.

  Low types care more about privacy, so they must not be assigned more data use to prevent deviations

- $\sim$ OB + monotone $a \Rightarrow$ seller must ensure that $a(\theta)$ is **non-decreasing** on the set of trading types

  This is because higher types call for higher actions from third party

Thus, IC and OB are **not in conflict** $\rightsquigarrow$ granular disclosure is feasible

Taking Stock

We showed how the sign of the privacy β plays crucial role in shaping

1. **Consumer rents:** Whether more data use helps or hurts consumers
2. **Data sharing:** Whether data disclosure is coarse or granular

Thus the privacy β shapes equilibrium and optimal regulation

Next, we analyze separately the two cases: **positive** and **negative**

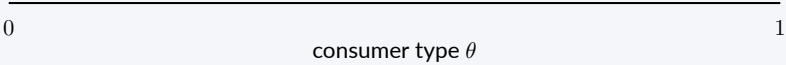

positive β

(higher types are more privacy-sensitive)

Equilibrium When $\beta > 0$

Proposition 3

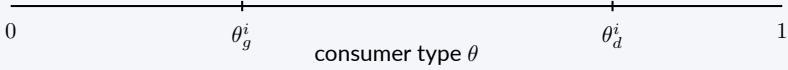

Fix $\beta > 0$ and a policy regime $i \in \{\text{A}, \text{B}, \text{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that a seller-optimal outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta > 0$

Proposition 3

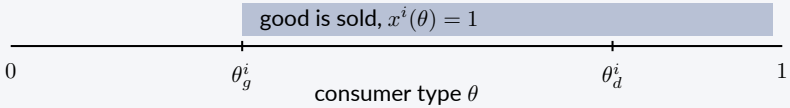

Fix $\beta > 0$ and a policy regime $i \in \{\text{A}, \text{B}, \text{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that a seller-optimal outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta > 0$

Proposition 3

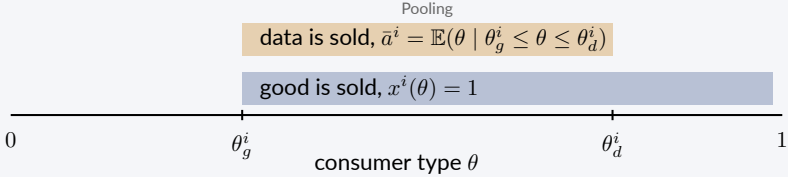

Fix $\beta > 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that a seller-optimal outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta > 0$

Proposition 3

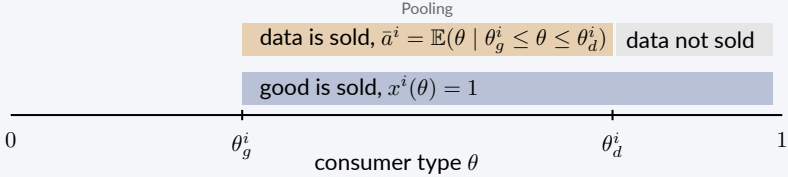

Fix $\beta > 0$ and a policy regime $i \in \{\text{A}, \text{B}, \text{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that a seller-optimal outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta > 0$

Proposition 3

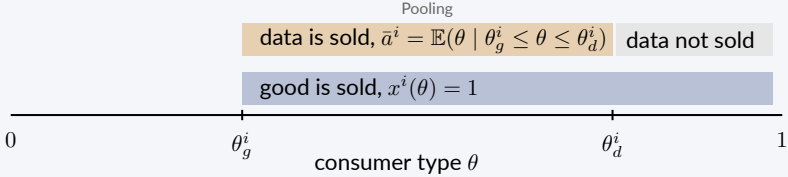

Fix $\beta > 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that a seller-optimal outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta > 0$

Proposition 3

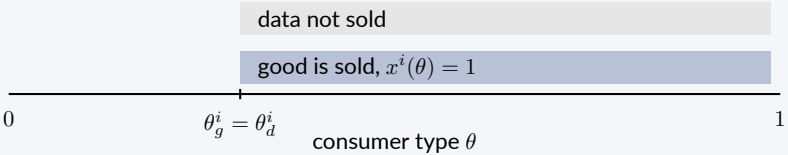

Fix $\beta > 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that a seller-optimal outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta > 0$

Proposition 3

Fix $\beta > 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that a seller-optimal outcome (x^i, a^i, t^i) is as follows:

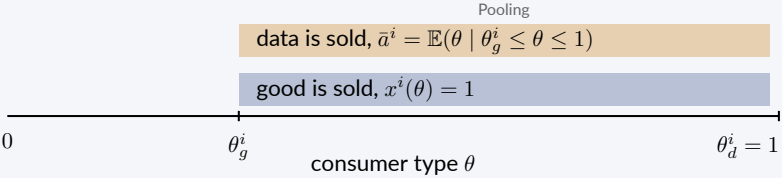

In particular, under **Data Ban**, $\theta_d^{\mathsf{B}} = \theta_g^{\mathsf{B}} \rightsquigarrow$ no data is sold

- No aftermarket $\Rightarrow$ standard monopoly pricing problem
- Simple posted price mechanism

Equilibrium When $\beta > 0$

Proposition 3

Fix $\beta > 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that a seller-optimal outcome (x^i, a^i, t^i) is as follows:

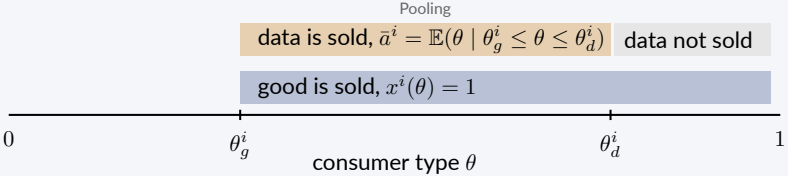

In particular, under **Data Anarchy**, $\theta_d^{\mathsf{A}} = 1 \rightsquigarrow$ all data is sold

- Monetization is coarse; consumers are pooled in same record
- Still posted price. Same treatment, same "compensation"

Equilibrium When $\beta > 0$

Proposition 3

Fix $\beta > 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that a seller-optimal outcome (x^i, a^i, t^i) is as follows:

In particular, under **Data Market**, $\theta_d^{\mathsf{M}} \in [\theta_g^{\mathsf{M}}, 1] \rightsquigarrow$ some data is sold

- Two versions of the good are offered: one is private, the other is not
- Private version attracts higher types, who are more privacy sensitive

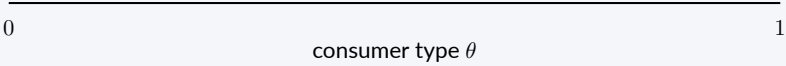

negative β

(higher types are less privacy-sensitive)

Equilibrium When $\beta \leq 0$

Proposition 4

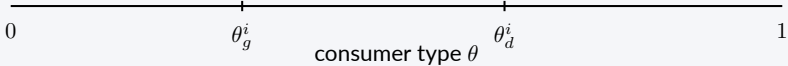

Fix $\beta \leq 0$ and a policy regime $i \in \{\text{A}, \text{B}, \text{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that an equilibrium outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta \leq 0$

Proposition 4

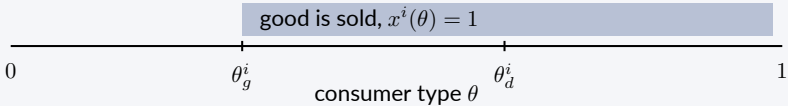

Fix $\beta \leq 0$ and a policy regime $i \in \{\text{A}, \text{B}, \text{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that an equilibrium outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta \leq 0$

Proposition 4

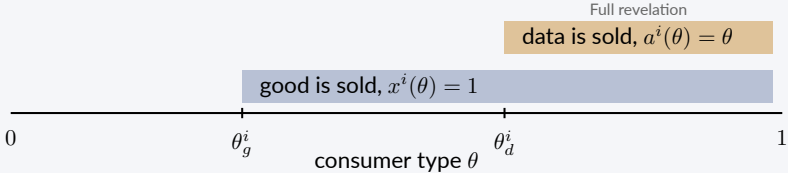

Fix $\beta \leq 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that an equilibrium outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta \leq 0$

Proposition 4

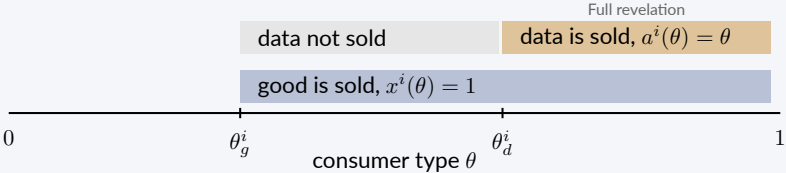

Fix $\beta \leq 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that an equilibrium outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta \leq 0$

Proposition 4

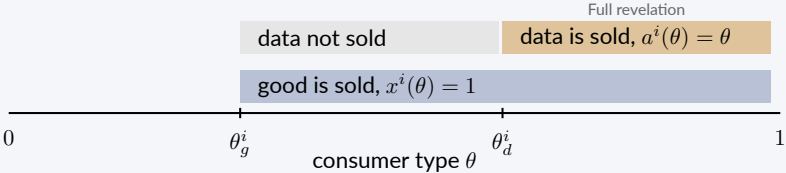

Fix $\beta \leq 0$ and a policy regime $i \in \{\text{A}, \text{B}, \text{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that an equilibrium outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta \leq 0$

Proposition 4

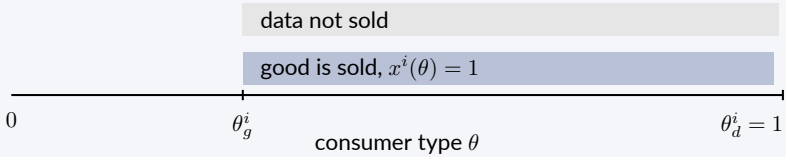

Fix $\beta \leq 0$ and a policy regime $i \in \{\text{A}, \text{B}, \text{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that an equilibrium outcome (x^i, a^i, t^i) is as follows:

Equilibrium When $\beta \leq 0$

Proposition 4

Fix $\beta \leq 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that an equilibrium outcome (x^i, a^i, t^i) is as follows:

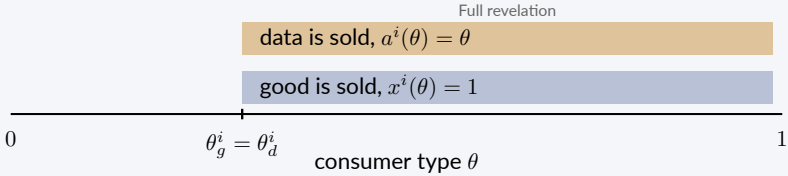

In particular, under **Data Ban**, $\theta_d^{\mathsf{B}} = 1 \rightsquigarrow$ no data is sold

- No aftermarket $\Rightarrow$ standard monopoly pricing problem
- Simple posted price mechanism

Equilibrium When $\beta \leq 0$

Proposition 4

Fix $\beta \leq 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that an equilibrium outcome (x^i, a^i, t^i) is as follows:

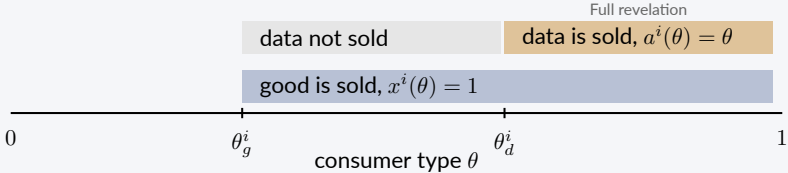

In particular, under **Data Anarchy**, $\theta_d^{\mathsf{A}} = \theta_g^{\mathsf{A}} \rightsquigarrow$ all data is sold

- Monetization is granular; third party learns θ (feasible vs optimal)
- Rich menu: each version with a different data use and compensation

Equilibrium When $\beta \leq 0$

Proposition 4

Fix $\beta \leq 0$ and a policy regime $i \in \{\mathsf{A}, \mathsf{B}, \mathsf{M}\}$. There exist cutoffs $\theta_g^i \leq \theta_d^i$ such that an equilibrium outcome (x^i, a^i, t^i) is as follows:

In particular, under **Data Market**, $\theta_d^{\mathsf{M}} \in [\theta_g^{\mathsf{M}}, 1] \rightsquigarrow$ some data is sold

- Many versions of the good are offered: one is private, the others are not
- Private version draws lower types, who are more privacy sensitive

welfare

How Policies Shape Welfare

What are the welfare implications of these policies?

Seller is weakly better off in Data Market (**Remark 1**)

Third party is indifferent across regimes

What about consumers?

How Policies Shape Welfare

What are the welfare implications of these policies?

Seller is weakly better off in Data Market (**Remark 1**)

Third party is indifferent across regimes

What about consumers?

- ∼ **Policy Puzzle:** Without further structure, each policy regime can be best for all consumers

Welfare Implications

Proposition 5

If $\beta \leq 0$

$\sim$ Data Market Pareto dominates Data Ban

If $\beta > 0$

$\sim$ Data Market Pareto dominates Anarchy (when β sufficiently small)

Welfare Implications

Proposition 5

If $\beta \leq 0$

- $\sim$ Data Market Pareto dominates Data Ban
- $\sim$ Types below a cutoff $\tilde{\theta}$ prefer Market; those above prefer Anarchy

If $\beta > 0$

- $\sim$ Data Market Pareto dominates Anarchy (when β sufficiently small)
- $\sim$ Types below a cutoff $\hat{\theta}$ prefer Market; those above prefer Ban

Welfare Implications

Proposition 5

If $\beta \leq 0$

- $\sim$ Data Market Pareto dominates Data Ban
- $\sim$ Types below a cutoff $\tilde{\theta}$ prefer Market; those above prefer Anarchy

  Test: Market Pareto dominates Anarchy iff $p^{\mathsf{M}}_{\min} \leq p^{\mathsf{A}}_{\min}$ (compare prices of cheapest versions)

If $\beta > 0$

- $\sim$ Data Market Pareto dominates Anarchy (when β sufficiently small)
- $\sim$ Types below a cutoff $\hat{\theta}$ prefer Market; those above prefer Ban

  Test: Market Pareto dominates Ban iff $p^{\mathsf{M}}_{\max} \leq p^{\mathsf{B}}$ (compare prices of private versions)

Summary

Therefore, Data Market has many desirable welfare properties

1. It is never Pareto dominated
2. It Pareto dominates either data anarchy or a data ban—with the sign of the privacy β determining which
3. When it is not Pareto dominant, it protects lower-valuation consumers

In this sense, establishing a data market emerges as an attractive policy choice, performing well across environments

conclusion

Conclusion

A central concern of privacy law is how to regulate third-party data sharing

A tractable framework to study third-party data sharing and optimal regulation

Positive Results:

- ∼ We identify a key structural parameter: the privacy β

  It shapes data monetization, consumer rents, and welfare rankings across policies

Normative Results:

- ∼ No single policy is best for all consumers in every environment
- ∼ Yet, **Data Markets** emerge as a robust, though imperfect, compromise
